

1        **PROCESS FOR PRODUCING A MALT BEVERAGE HAVING IMPROVED**  
2        **FOAMING PROPERTIES AND PRODUCT PRODUCED THEREFROM**

3  
4        **FIELD OF THE INVENTION**

5            The present invention relates generally to the production of beer, and more  
6        particularly to the production of beer having improved foaming properties. The invention  
7        has particular utility in the production of beer and will be described in connection with  
8        such utility, although the invention also may be advantageously used in the production of  
9        other malt beverages.

10  
11       **DESCRIPTION OF THE INVENTION**

12           In the production of beer, yeast is used to ferment a substrate made of a mixture of  
13        fermentable carbohydrates, "wort carbohydrates" into ethyl alcohol. The wort  
14        carbohydrates which can be fermented by Brewers' yeast are normally maltose, glucose,  
15        maltotriose and traces of sucrose and fructose. They are obtained by allowing malt  
16        enzymes to transform starch molecules from malt and other adjuncts into the fermentable  
17        sugars outlined above. This is done during the mashing operation.

18           Conventional mashing involves mixing together of malt and cereal adjuncts in hot  
19        water, followed by a series of heating and resting cycles. Substances which are  
20        solubilized in the hot water are collectively called the extract. Following mashing, the  
21        soluble materials are extracted in a lauter tub and sparged with hot water, leaving behind  
22        the spent grain. A clear liquid (wort) obtained by the extraction may then be transferred  
23        to a brew kettle and boiled for a period of time which inactivates the malt enzymes. Wort

1 compositions vary depending on the raw materials and mash cycle employed.

2       A typical wort used in brewing may comprise the mixed extract of a barley malt  
3 mash and a cereal adjuncts mash typically of corn grits or rice. Such mixed extract may  
4 be obtained by treating a kiln dried barky malt with warm water, at about 50°C., in one  
5 vessel, the mash tub, and boiling the cereal adjuncts, (e.g. corn grits or rice) in another  
6 vessel, the so-called "cooker," and then adding the boiling contents of the cooker to the  
7 warm water suspension in the mash tub. This serves to raise the temperature of the mash  
8 tub contents to about 57-67°C. During the rise from 50°C., to about 67°C., and starting  
9 at around 63°C., the enzymes in the malt and in particular beta-amylase which is most  
10 active between 60°C and 70°C., partially degrade the starches in both the malt itself and  
11 in the corn grits or rice to form simple fermentation sugars, primarily glucose, fructose  
12 and maltose. These simple sugars are fairly sweet tasting, and also are fermentable by  
13 Brewers' yeast to alcohol and carbon dioxide.

14       The combined mash is then filtered in a lauter tub, mash filter or other means and  
15 the resulting wort boiled with hops, filtered, cooled and fermented with yeast after a  
16 period of rest, where beer is stored cold and the yeast is allowed to settle out, the beer  
17 filtered, once or twice, and then carbonated.

18       Carbonated malt beverages produce a more or less long-lasting foam when poured  
19 into a drinking glass. This foam has always been considered a desirable attribute in such  
20 beverages. Carbonating enhances the flavor and mouth feel and adds to the consumer's  
21 perception of freshness. A flat beer looks and tastes stale. Prior to the present invention,  
22 the only agents known to improve the foaming properties have been gums such as acacia  
23 or alginate, or a metal salt, such as ferrous ammonium sulfate, or ginseng. However, such

1 agents may adversely affect taste and / or increase turbidity of the resulting beverage  
2 product and thus are not entirely satisfactory.

3

#### 4 **OBJECT OF THE INVENTION**

5 It is thus a primary object of the present invention to provide a new and improved  
6 process for improving the foaming properties of a beverage. Another object of the present  
7 invention is to provide a novel and improved method for increasing the foam life of a  
8 malt beverage. A specific object of the present invention is to provide a beverage which  
9 is characterized by improved foaming characteristics.

10

#### 11 **BRIEF SUMMARY OF THE INVENTION**

12 Generally, in accordance with the present invention, I have found that the addition  
13 of caffeine to a malt beverage, e.g., beer or ale, during the normal brewing processes  
14 produces a finished beverage of improved foaming properties.

15

#### 16 **DETAILED DESCRIPTION OF THE INVENTION**

17 Caffeine is a naturally occurring alkaloid that is found in coffee beans, tea leaves,  
18 cocoa beans, maté leaves, guarana beans and kola nuts. Caffeine, which is chemically  
19 1, 3, 7-tri-methylxanthine, has the formula:

20

21

22

1 is odorless, and has a bitter taste, is slightly soluble in water and in alcohol, which makes  
2 it quite compatible as an addition to beer. Caffeine is available commercially as a by-  
3 product of decaffeinated coffee manufacture.

4 Caffeine has several pharmacological actions. It has a stimulating action on the  
5 central nervous system. It has important actions on the cardiovascular system. It has  
6 some importance in relaxing smooth muscle and in increasing diuresis.

7 It has now been found that the addition of caffeine during the normal brewing  
8 process produces a beer with improved foaming properties, without effecting flavor.

9 The caffeine may be added at any stage of the brewing process. It may be added  
10 to the mashing cycle before the kettle. It may be added to the kettle and boiled with hops.  
11 It may also be added during the fermentation or aging stage, and since it is readily soluble  
12 in water it may be added in the finishing stage. The foaming improvement appears to be  
13 dependant on the quantity of caffeine added wherever it is used. Preferably, the caffeine  
14 may be added in an amount within the range of 10 milligrams to 300 milligrams per 12  
15 ounces of finished beverage, more preferably 20 to 100 milligrams per 12 ounces of  
16 finished beverage may be used also. The foaming improvement appears to be contingent  
17 on the quantity of caffeine added. The reason for the improvement of foaming by the  
18 addition of the caffeine during the brewing process is not understood. In other beverages,  
19 be they coffee, tea or cola drinks, improvement of foaming has not been observed.

20 These quantities of caffeine also may be expressed as 35.5 parts per million to  
21 1000 parts per million by weight of the finished beverage, preferably 71 to 355 ppm by  
22 weight of caffeine.

Addition of more than about 300 milligrams per 12 ounces of finished beverage (1000 ppm) appears to add little additional improvement of foaming.

The present invention will be further described in the following working examples.

The following examples, illustrative of the present invention, employ a conventional brew house having a mash tub and cereal cooker or boiler vessel. The basic procedure was to suspend dried, ground barley malt in water, heat the resulting suspension to about 50° C for a period of time.

In Example I, the cereal adjuncts, i.e. corn grits, which have been boiled in a separate cereal cooker or boiler vessel, are added to the malt slurry. The combined mash is heated for a period of time and then transferred to a filtering vessel or lauter tub. The clear liquid which drains from the mash, and the hot water used to wash the adhering liquid from the grains are run into a kettle and boiled. The hops and caffeine are added during the boiling period. The liquid is again strained, cooled and treated with yeast and fermented. In Example II the barley malt is ground in the mill and mashed with water at about 51°C. The temperature is raised and the malt slurry is transferred to a mash filter. The filtered liquid is run into a kettle, and cereal adjuncts in the form of corn syrup added. The combined mash is heated for a period of time and then transferred to a filtering vessel or lauter tub where the liquid is strained, cooled and allowed to ferment. The fermented liquid is filtered, and treated with a hot water solution of caffeine.

### EXAMPLE I

3,000 lbs. of corn grits were added to 60 barrels of water, and the resulting mixture heated to boiling, with stirring, for 30 minutes in a cereal cooker.

1 Concurrently, 5,000 lbs. of ground barley malt were added to 60 bbls. of water,  
2 and heated to 50°C., with stirring, in a mash tub. The resulting malt mash was held at  
3 50°C. for 15 minutes, and the contents of the cereal cooker were then rapidly pumped  
4 over into the mash tub. The combined mash was held at 63°C. for 30 minutes, and then  
5 heated to 75°C. and transferred to a lauter tub. A clear liquid, drained from the mash and  
6 hot water used to wash the adhering liquid from the grains are run into a kettle and boiled  
7 for 90 minutes. Sixty lbs. of hops and 6.0 lbs. of caffeine are added during the boiling  
8 period.

9 The resulting liquid is again strained, cooled to about 9°C, and transferred to a  
10 fermentation tank to which was added one hundred lbs. of brewers' yeast. The resulting  
11 mixture was allowed to ferment for seven days. After letting the yeast settle out, and  
12 filtering, the resulting filtrate beer was bottled.

13 In a time and pour test, the caffeine-treated beer foam lasted 5 minutes, while beer  
14 produced under identical conditions, but without the addition of caffeine, the foam lasted  
15 only 3 minutes.

## 16 **EXAMPLE II**

17 2,500 lbs. of ground barley malt were added to 30 bbls. of water, and heated to  
18 51°C. The temperature of the mash was raised to 75°C., and the mash transferred to a  
19 mash filter. The filtered liquid was run into a kettle and 140 gallons of corn syrup added.  
20 The resulting combined mash was then boiled for 60 minutes. The resulting liquid was  
21 strained, cooled to about 11°C., and transferred to a fermentation tank to which was  
22 added 90 lbs. of brewers' yeast. The resulting mixture was allowed to ferment for seven  
23 days. The fermented liquid was then filtered, and treated with a hot water solution of 10.0

1 lbs. of caffeine. The treated liquid was held at 1°C. for 24 hours, and the liquid was then  
2 filtered, packaged and cooled.

3 In a pour test, the caffeine-treated malt beverage foam lasted 5 1/2 minutes while  
4 malt beverage produced under identical conditions, but without the addition of caffeine,  
5 lasted on 3 minutes.

6 Certain changes may be made without departing from the scope of the invention  
7 herein involved. It is therefore intended that all matter contained in the above description  
8 shall be interpreted as illustrative and not in a limiting sense.

9
